Radiolaria

O. Roger Anderson

Radiolaria O. Roger Anderson

The study of marine plankton has traditionally focused on those organisms that appeared to have obvious ecological significance in understanding the major patterns of biological productivity, trophic relations, community structure, and the dynamic interaction of living things with the physical environment. Not infrequently, this thrust has centered on the apparently most abundant and/or larger members of the plankton community, including significant primary producers such as the diatoms, nonthecate algae, and flagellates, or the major consumers--copepods, gelatinous metazoa, and other abundant metazoan invertebrates.

Consequently, some of the less well recognized but also abundant microzooplankton have been given less attention. The radiolaria, although widely studied as fossils by micropaleontologists, have in modern times. This has been relatively neglected by biologists, probably given their widespread distribution in the oceans, remarkably complex form, and not infrequently localized abundance. Their diversity of form, encompassing solitary species of microscopic dimensions and colonial species as large as several centimeters or more, challenges us to explain their evolutionary origins, explore their structural-functional correlates, and comprehend the ecological basis for their wide spread occurrence in all oceans of the world from the greatest depth to the surface of the sea. Their intricate and aesthetically pleasing skeletons of enormous variety and fine-detailed design formed from amorphous silica (opaline glass) offer a unique biomineralized product that defies immediate biological explanation.
